Abstract

Frequency domain Blind Source Separation (BSS) is shown to be equivalent to two sets of frequency domain adaptive microphone arrays, i.e., Adaptive Null Beamformers (ANB). The minimization of the off-diagonal components in the BSS update equation can be viewed as the minimization of the mean square error in the ANB. The unmixing matrix of the BSS and the filter coefficients of the ANB converge to the same solution in the mean square error sense if the two source signals are ideally independent. Therefore, we can conclude that the performance of the BSS is upper bounded by that of the ANB. This understanding clearly explains the poor performance of the BSS in a real room with long reverberation. The fundamental difference exists in the adaptation period when they should adapt. That is, the ANB can adapt in the presence of a jammer but the absence of a target, whereas the BSS can adapt in the presence of a target and jammer, and also in the presence of only a target.

1. Introduction

Blind Source Separation (BSS) is an approach to estimate source signals \( s_i(t) \) using only the information of mixed signals \( x_j(t) \) observed in each input channel. This technique is applicable to the achievement of noise robust speech recognition and high-quality hands-free telecommunication systems. It might also become a cue for auditory scene analysis.

To achieve the BSS of convolutive mixtures, several methods have been proposed [1, 2]. In this paper, we consider the BSS of convolutive mixtures of speech in the frequency domain [3, 4], for the sake of mathematical simplicity and the reduction of computational complexity.

Signal separation by using a noise cancellation framework with signal leakage into the noise reference was discussed in [5, 6]. It was shown that the least squares criterion is equivalent to the decorrelation criterion of a noise free signal estimate and a signal free noise estimate. The error minimization was shown to be completely equivalent with a zero search in the crosscorrelation.

2. Frequency domain BSS of convolutive mixtures of speech

The signals recorded by \( M \) microphones are given by

\[
x_j(n) = \sum_{i=1}^{N} \sum_{p=1}^{P} h_{ji}(p)s_i(n-p+1) \quad (j = 1, \cdots, M),
\]

where \( s_i \) is the source signal from a source \( i \), \( x_j \) is the received signal by a microphone \( j \), and \( h_{ji} \) is the \( P \)-point impulse response from source \( i \) to microphone \( j \). In this paper, we consider a two-input, two-output convolutive BSS problem, i.e., \( N = M = 2 \) (Fig. 1).

The frequency domain approach to the convolutive mixture is to transform the problem into an instantaneous BSS problem in the frequency domain [3, 4]. Using a \( T \)-point short time Fourier transform for (1), we obtain

\[
X(\omega, m) = H(\omega)S(\omega, m).
\]

We assume that \( H(\omega) \) is invertible, and \( H_{ji}(\omega) \neq 0 \).
The unmixing process can be formulated in a frequency bin $\omega$:

$$Y(\omega, m) = W(\omega)X(\omega, m), \quad (3)$$

where $S(\omega, m) = [S_1(\omega, m), S_2(\omega, m)]^T$ is the source signal, $X(\omega) = [X_1(\omega), X_2(\omega)]^T$ is the observed signal, $Y(\omega) = [Y_1(\omega), Y_2(\omega)]^T$ is the estimated source signal, and $W(\omega)$ represents the unmixing matrix at frequency bin $\omega$. $W(\omega)$ is determined so that $Y_1(\omega, m)$ and $Y_2(\omega, m)$ become mutually independent. The above calculations are carried out at each frequency independently.

### 2.1. Second Order Statistics (SOS)

It is well known that the decorrelation criterion is insufficient to solve the problem. In [6], however, it is pointed out that non-stationary signals provide enough additional information to estimate all $W_{ij}$. Some authors have utilized the SOS for mixed speech signals [7, 8].

The source signals $S_1(\omega, m)$ and $S_2(\omega, m)$ are assumed to be zero mean and mutually uncorrelated, that is,

$$R_S(\omega, k) = \frac{1}{M} \sum_{m=0}^{M-1} S(\omega, Mk + m)S^*(\omega, Mk + m) = \Lambda_s(\omega, k), \quad (4)$$

where $\Lambda_s(\omega, k)$ is a different diagonal matrix for each $k$.

In order to determine $W(\omega)$ so that $Y_1(\omega, m)$ and $Y_2(\omega, m)$ become mutually uncorrelated, we seek a $W(\omega)$ that diagonalizes the covariance matrices $R_Y(\omega, k)$ simultaneously for all $k$,

$$R_Y(\omega, k) = W(\omega)R_X(\omega, k)W^*(\omega) = W(\omega)H(\omega)\Lambda_s(\omega, k)H^*(\omega)W^*(\omega) = \Lambda_c(\omega, k), \quad (5)$$

where $R_X$ is the covariance matrix of $X(\omega)$ as follows,

$$R_X(\omega, k) = \frac{1}{M} \sum_{m=0}^{M-1} X(\omega, Mk + m)X^*(\omega, Mk + m), \quad (6)$$

and $\Lambda_c(\omega, k)$ is an arbitrary diagonal matrix.

The diagonalization of $R_Y(\omega, k)$ can be written as an overdetermined least-square problem,

$$\arg \min_{W(\omega)} \sum_k |\text{off-diag}W(\omega)R_X(\omega, k)W^*(\omega)|^2 \quad (7)$$

where $|x|^2$ is the squared Frobenius norm. The least squares solution to (7) is obtained using the steepest descent algorithm,

$$W_{t+1}(\omega) = W_t(\omega) - \mu(\omega) \frac{\partial}{\partial W} \sum_k J_l(\omega, k), \quad (8)$$

where $J_l(\omega, k) = |\text{off-diag}W(\omega)R_X(\omega, k)W^*(\omega)|^2$.

### 3. Frequency domain adaptive null beamformer

Here, we consider the frequency domain adaptive null beamformer (ANB), which forms a null directivity pattern towards a jammer. Since our aim is to separate two signals $S_1$ and $S_2$ with two microphones, two sets of ANB are used (Fig. 2), that is, an ANB that forms a null directivity pattern towards source $S_2$ by using filter coefficients $W_{11}$ and $W_{12}$, and an ANB that forms a null directivity pattern towards source $S_1$ by using filter coefficients $W_{21}$ and $W_{22}$. Note that an ANB can be adapted when only a jammer exists but a target does not exist.

#### 3.1. ANB null towards $S_2$

First, we consider the case of target $S_1$ and jammer $S_2$ [Fig. 2(a)]. When target $S_1 = 0$, output $Y_1(\omega, t)$ is expressed as

$$Y_1(\omega, t) = W_{11}(\omega)X_1(\omega, t) + W_{12}(\omega)X_2(\omega, t)$$

$$= W(\omega)X(\omega, t), \quad (9)$$

where $W(\omega) = [W_{11}(\omega), W_{12}(\omega)]$, $X(\omega, t) = [X_1(\omega, t), X_2(\omega, t)]^T$.

To minimize jammer $S_2(\omega, t)$ in output $Y_1(\omega, t)$ when target $S_1 = 0$, mean square error $J(\omega)$ is introduced as

$$J(\omega) = E[Y_1^2(\omega, t)]$$

$$= W(\omega)E[X(\omega, t)X^*(\omega, t)]W^*(\omega)$$

$$= W(\omega)R(\omega)W^*(\omega), \quad (10)$$

where $E$ is the expectation and

$$R(\omega) = E \left[ \begin{array}{cc} X_1(\omega, t) & X_1(\omega, t)X_2(\omega, t) \\ X_2(\omega, t) & X_2(\omega, t)X_2(\omega, t) \end{array} \right]. \quad (11)$$

By differentiating cost function $J(\omega)$ with respect to $W$ and setting the gradient equal to zero

$$\frac{\partial J(\omega)}{\partial W} = 2RW^* = 0, \quad (12)$$

$$W_{t+1}(\omega) = W_t(\omega) - \mu(\omega) \frac{\partial}{\partial W} \sum_k J_l(\omega, k),$$

Figure 2: Two sets of ANB system configurations.

(a) ANB for a target $S_1$ and a jammer $S_2$.

(b) ANB for a target $S_2$ and a jammer $S_1$. 

Eurospeech 2001 - Scandinavia
we obtain the equation to solve as follows \([\omega, t]\), etc., are omitted for convenience]:

\[
E \begin{bmatrix} X_1X_1^t & X_1X_2^t & X_2X_1^t & X_2X_2^t \end{bmatrix} \begin{bmatrix} W_{11}^t \\ W_{12}^t \\ W_{21}^t \\ W_{22}^t \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix},
\]

(13)
or in a separate formula

\[
E[X_1X_1^t]W_{11}^* + E[X_1X_2^t]W_{12}^* = 0
\]

(14)
\[
E[X_2X_1^t]W_{11}^* + E[X_2X_2^t]W_{12}^* = 0.
\]

(15)

Using \(X_1 = H_{12}S_2, X_2 = H_{22}S_2\), we get

\[
W_{11}H_{11} + W_{12}H_{21} = c_1,
\]

(16)

where \(c_1\) is an arbitrary complex constant. Since \(H_{12}\) and \(H_{22}\) are unknown, the minimization of (10) with adaptive filters \(W_{11}\) and \(W_{12}\) is used to derive (16) with constraint (18). This means that the ANB solution is derived from simultaneous equations (16) and (18).

3.2. ANB null towards \(S_1\)

Similarly for target \(S_2\), jammer \(S_1\), and output \(Y_2\) [Fig. 2(b)], we obtain

\[
W_{21}H_{11} + W_{22}H_{21} = 0 \quad (19)
\]

\[
W_{21}H_{12} + W_{22}H_{22} = c_2. \quad (20)
\]

3.3. Two sets of ABF

By combining (16), (18), (19), and (20), the simultaneous equations for two sets of ANB are summarized as

\[
\begin{bmatrix} W_{11} & W_{12} \\ W_{21} & W_{22} \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} = \begin{bmatrix} c_1 & 0 \\ 0 & c_2 \end{bmatrix}. \quad (21)
\]

4. Equivalence between Blind Source Separation and Adaptive Null Beamformers

The BSS update equation (8) works to minimize off-diagonal components in

\[
E \begin{bmatrix} Y_1Y_1^t & Y_1Y_2^* \\ Y_2Y_1^t & Y_2Y_2^* \end{bmatrix}.
\]

(22)

In the BSS framework, outputs \(Y_1\) and \(Y_2\) are expressed as

\[
Y_1 = aS_1 + bS_2
\]

(23)
\[
Y_2 = cS_1 + dS_2,
\]

(24)

where

\[
\begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} W_{11} & W_{12} \\ W_{21} & W_{22} \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix}.
\]

(25)

4.1. When \(S_1 \neq 0\) and \(S_2 \neq 0\)

We now analyze what is going on in the BSS framework. After convergence, the expectation of the off-diagonal component \(E[Y_1Y_2^*]\) is expressed as

\[
E[Y_1Y_2^*] = ad^*E[S_1S_2^*] + bc^*E[S_2S_1^*] + (ac^*E[S_1^2] + bd^*E[S_2^2])
\]

(26)

Since \(S_1\) and \(S_2\) are assumed to be uncorrelated, the first term and the second term become zero. Then, the BSS adaptation should drive the third term of (26) to be zero. By squaring the third term and setting it equal to zero

\[
(ac^*E[S_1^2] + bd^*E[S_2^2])^2 = a^2c^2(E[S_1^2])^2 + 2abc^*d^*E[S_1^2]E[S_2^2] + b^2d^2(E[S_2^2])^2 = 0
\]

(27)

(27) is equivalent to

\[
ac^* = bd^* = 0, \quad abc^*d^* = 0.
\]

(28)

**CASE 1:** \(a = c_1, c = 0, b = 0, d = c_2\)

\[
\begin{bmatrix} W_{11} & W_{12} \\ W_{21} & W_{22} \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} = \begin{bmatrix} c_1 & 0 \\ 0 & c_2 \end{bmatrix}
\]

(29)

This equation is exactly the same as that of the ANB (21).

**CASE 2:** \(a = 0, c = c_1, b = c_2, d = 0\)

\[
\begin{bmatrix} W_{11} & W_{12} \\ W_{21} & W_{22} \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} = \begin{bmatrix} 0 & c_2 \\ c_1 & 0 \end{bmatrix}
\]

(30)

This equation leads to the permutation solution which is

\[
Y_1 = c_2S_2, Y_2 = c_1S_1.
\]

**CASE 3:** \(a = 0, c = c_1, b = 0, d = c_2\)

\[
\begin{bmatrix} W_{11} & W_{12} \\ W_{21} & W_{22} \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ c_1 & c_2 \end{bmatrix}
\]

(31)

This equation leads to undesirable solution \(Y_1 = 0, Y_2 = c_1S_1 + c_2S_2\).

**CASE 4:** \(a = c_1, c = 0, b = c_2, d = 0\)

\[
\begin{bmatrix} W_{11} & W_{12} \\ W_{21} & W_{22} \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} = \begin{bmatrix} c_1 & c_2 \\ 0 & 0 \end{bmatrix}
\]

(32)

This equation leads to undesirable solution \(Y_1 = c_1S_1 + c_2S_2, Y_2 = 0\).

Note that CASE 3 and CASE 4 do not appear in general since we assume that \(H(\omega)\) is invertible, and \(H_p(\omega) \neq 0\). That is, if \(a = 0\) then \(b \neq 0\) (CASE 2), and if \(c = 0\) then \(d \neq 0\) (CASE 1).

If the uncorrelated assumption between \(S_1(\omega)\) and \(S_2(\omega)\) collapses, the first and second terms of (26) become the bias noise to get the correct coefficients \(a, b, c, d\).
4.2. When $S_1 \neq 0$ and $S_2 = 0$

The BSS can adapt, even if there is only one active source. In this case, only one set of ANB is achieved.

When $S_2 = 0$, we have

$$Y_1 = aS_1 \quad \text{and} \quad Y_2 = cS_1$$

(33)

then

$$E[Y_1Y_1^*] = E[aS_1c^*S_1^*] = ac^*E[S_1^2] = 0,$$

(34)

and therefore, the BSS adaptation should drive

$$ac^* = 0.$$  

(35)

CASE 5: $c = 0, a = c$

$$
\begin{bmatrix}
W_{11} & W_{12} \\
W_{21} & W_{22}
\end{bmatrix}
\begin{bmatrix}
H_{11} & H_{12} \\
H_{21} & H_{22}
\end{bmatrix}
= \begin{bmatrix}
c_1 & * \\
0 & *
\end{bmatrix},$$  

(36)

where * shows a don’t care. Since $S_2 = 0$, the output can be derived correctly $Y_1 = c_1S_1, Y_2 = 0$ as follows.

$$
\begin{bmatrix}
Y_1 \\
Y_2
\end{bmatrix}
= \begin{bmatrix}
c_1 & * \\
0 & *
\end{bmatrix}
\begin{bmatrix}
S_1 \\
0
\end{bmatrix}
= \begin{bmatrix}
c_1S_1 \\
0
\end{bmatrix}
$$

(37)

CASE 6: $c = c_1, a = 0$

$$
\begin{bmatrix}
W_{11} & W_{12} \\
W_{21} & W_{22}
\end{bmatrix}
\begin{bmatrix}
H_{11} & H_{12} \\
H_{21} & H_{22}
\end{bmatrix}
= \begin{bmatrix}
0 & * \\
0 & c_1 & *
\end{bmatrix},$$  

(38)

This equation leads to the permutation solution which is

$$Y_1 = 0, Y_2 = c_1S_1.$$

(39)

4.3. Fundamental limitation of frequency domain BSS

Frequency domain BSS and frequency domain ANB are shown to be equivalent [see equations (21) and (29)] if the independent assumption ideally holds [see equation (26)]. Moreover, we have shown in [9], that a long frame size works poorly in frequency domain BSS for speech data of a few seconds, because the assumption of independency between $S_1(\omega)$ and $S_2(\omega)$ does not hold in each frequency. Therefore, the performance of the BSS is upper bounded by that of the ANB.

We can form only one null towards the jammer in the case of two microphones. Although the directivity pattern becomes duller when there is a long reverberation, the BSS and ANB mainly remove the sound from the jammer direction. This understanding clearly explains the poor performance of the BSS in a real room with long reverberation.

The BSS was shown to outperform a fixed null beamformer that forms a steep null directivity pattern towards a jammer under the assumption of the jammer’s direction being known [10, 11]. It is well known that an adaptive null beamformer outperforms a fixed null beamformer in long reverberation. Our understanding also clearly explains the result.

Our discussion here is essentially also true for the BSS with Higher Order Statistics (HOS), and will be extended to it shortly.

5. Conclusion

Frequency domain Blind Source Separation (BSS) is shown to be equivalent to two sets of frequency domain adaptive null beamformers (ANB). The unmixing matrix of the BSS and the filter coefficients of the ANB converge to the same solution in the mean square error sense if the two source signals are ideally independent. This understanding clearly explains the poor performance of the BSS in a real room with long reverberation. The fundamental difference exists in the adaptation period when they should adapt. That is, the ANB can adapt in the presence of a jammer but the absence of a target, whereas the BSS can adapt in the presence of a target and jammer, and also in the presence of only a target.
